

# Modeling as data compression

- ▶ the model is a concise representation of the data
- ▶ exact model  $\leftrightarrow$  lossless compression (*e.g.*, zip)
- ▶ approximate model  $\leftrightarrow$  lossy compression (*e.g.*, mp3)

# Example: compression of a random vector

- ▶ data:  $1 \times n$  vector, generated by `randn`
- ▶ compression in `mat` format

	length $n$	1	223	334	556	667	1000
1.	original size	8	1784	2672	4448	5336	8000
2.	mat file size	178	1945	2798	4490	5341	7893

# Example: low-rank matrix compression

- ▶ data: random  $100 \times 100$  matrix  $D$  of rank 5
- ▶ stored in four different ways

	representation	size
1.	all elements of $D$	80000
2.	$D$ in <code>mat</code> format	75882
3.	all elements of $P$ and $L$	8024
4.	$P$ and $L$ in <code>mat</code> format	7767

- ▶ in 2 and 4, we compute a rank revealing factorization

$$D = PL$$

- ▶ can we do better than storing  $P$  and  $L$  (compressed)?

# Example: trajectory of an LTI system

- ▶ data: impulse response of a random 3rd order system
- ▶ stored in four different ways

	representation	size
1.	impulse response $h$	192
2.	$h$ in <code>mat</code> format	377
3.	model parameters $\theta$	56
4.	$\theta$ in <code>mat</code> format	233

- ▶ in 3 and 4, we have parameterized the system
